

My Tetris Puzzle

Interesting ways my polyomino (E piece) interact with Tetris™ systems:

- My polyomino can fit into many gaps, there is rarely a situation in regular tetris (non big bang) where it would not be able to fit on your board, it can fill either a single cell gap, 2 gaps with one cell in between, or three gaps each with one cell in between.
- The strange 5 tall shape however can make it dangerous at the top of your board.
- If you place my polyomino vertically at the edge of a board it blocks off an empty cell.
- My polyomino can stack with itself at any rotation given it has space to

Interesting relationships between the piece sequence and board state:

- When the player is given their second T piece there will be a temptation to drop it right into the well to clear 2 lines but if they do that they won't be able to clear the board.
- The player has to make many of their wells either from my polyomino or with the T pieces.

How my board state provides an interesting challenge:

- In big bang the player is going as quick as possible to reduce the other player's health, because of the large holes in my board state and the player's ability to hold pieces it could be easy for the player to misjudge the rotation or order.
- Because of the large holes and the player's ability to see the next pieces coming, the player has to think through how the pieces fit together in the block before placing.
- Because my piece can fit at any rotation the player may use it where it fits but also where it blocks the solution.

Pro play implications:

← E-spin quintuple setup

If brought to tetris the E piece could create a meta around E spinning as it would give extra points similar to a T-spin triple while clearing 5 lines.
